This report replaces report 17.0431-revised, dated August 30th, 2019.

SHR operates according to NEN-EN-ISO/IEC 17025.

Contents

1 Assignment

On September 16th, 2017 the project *Laboratoriumonderzoek t.b.v. Surinaamse Lesser Known Timber Species*, was granted and on March 2nd 2018 a specification was given of the work executed for this project and reported here.

2 Execution of the test

2.1 Identification and description of the samples

On January 25th, 2018, Mr. van Benthem (Probos) and Mr. Klaassen (SHR) inspected the timber just delivered from Suriname on the site of WTP (World Timber Products) at Hardenberg. Eight boards were chosen as material for investigation. Figure 2.1 shows the boules (stickered boards).

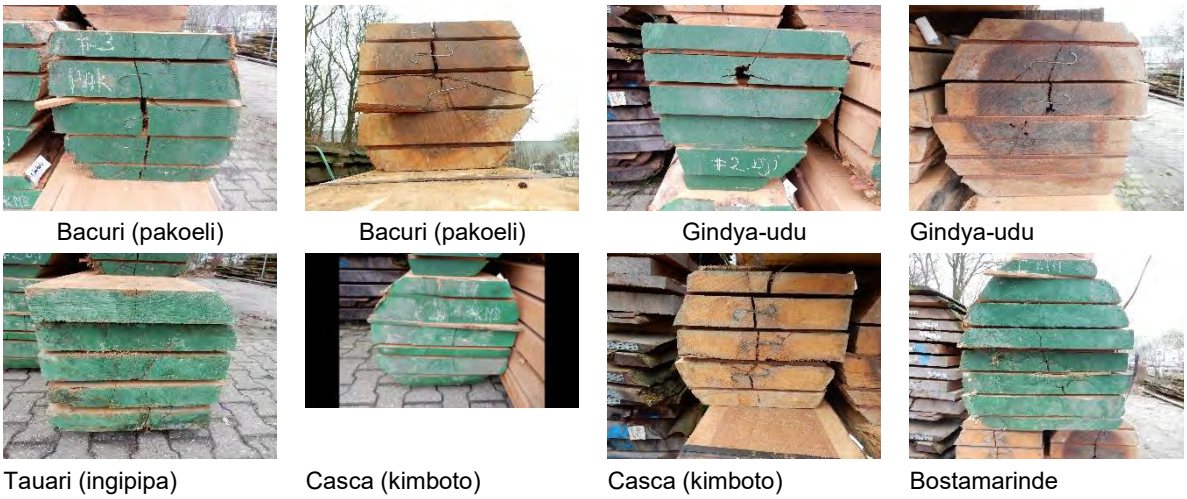

Figure 2.1 The stems on the site of WTP

From each stem the middle plank was selected for the lot assessment. Before transportation to SHR, these unedged boards were sawn into separate beams.
At the SHR laboratory, the beams were stored in the laboratory (at 20°C and 65% RH, appr. 2 months) until the lot assessment. During storage some fungal growth was seen and cracks appeared in some of the beams.
The lot assessment was mainly executed on March 23rd 2018.

For determination of the swelling and shrinkage, quarter sawn blocks (10mm thick in axial direction and 20-45mm wide) were made. All samples were numbered in agreement with the code used at the lot assessment. The number of samples used in the test depended on the wood quality. An overview of the samples is given in table 2.1.

Table 2.1 sample overview

Trade name	Code stem	Number of samples
Ingipipa	1.1	12
Bostamarinde	2.1	12
Gindya-udu	4.1 & 6.1	26
Pakoeli	5.1 & 5.2	14
Kimboto	3.1 & 7.1	10

For the durability tests samples were made according to the description of CEN/TS 15083-1 with dimensions 25 x 15 x 50 mm (w x t x l). Sample preparation started with a lath of each of the selected beams, which would deliver enough samples to use at least one sample on each of the required fungi, and two samples to determine moisture content. After conditioning, the laths were first calibrated (to 15x25 mm) and then crosscut to obtain the samples of 50 mm in length.
Untreated pine sapwood (*Pinus sylvestris*) and beech (*Fagus sylvatica*) samples of the same dimensions were prepared as virulence control samples. Wood for these samples was taken from the SHR stock. The virulence control samples are placed on the fungi without the presence of test samples and are used to check the activity of the fungi in the test.

2.2 Period of the test

The tests were conducted between March and November 2018.

2.3 Procedure

The lot assessment (according to SKH Publication 97-04):
On planed, coded samples, the quality of the timber was assessed, the imperfections found in the timber were described and pictures were taken both from normal wood as well as wood with imperfections. A representative sample was chosen for microscopic research. Based on the cross, radial, and tangential thin sections an anatomical description was made. Furthermore representative samples were chosen for making macroscopic pictures of the cross, flat and quarter sawn surfaces. Only the cross section picture was enlarged and an area of 5x5 mm is shown.

Determination of the radial and tangential swelling (according to SKH Publication 97-04):
Of the quarter sawn samples the mass as well as the radial and tangential dimensions were determined. Half of the samples were climatized to the following climates descending in humidity: 94% RH, 81% RH, 65% RH, 50% RH and 30% RH. The other half of the samples were climatized to another climates sequence with humidity ascending: 30% RH, 50% RH, 65% RH, 81% RH and 94% RH. If the mass of the samples did not change in 24 hours, the samples were regarded as climatized. Finally the samples were water saturated by submerging them in water for 24 hours, followed by oven drying for 24 hours at 103±2°C.
After every climatizing step and after water saturating the tangential and radial dimensions and the mass of the samples were determined. After oven drying, the samples were cooled in an desiccator and again the dimensions and mass were determined.

For determination of the thickness swelling and shrinkage the following formulas were used:

$$K_{x-y} = \frac{b_x - b_y}{b_x} * 100\%$$

$$Z_{x-y} = \frac{b_x - b_y}{b_y} * 100\%$$

Where b_x is the tangential or radial dimension at moisture content x and b_y is the tangential or radial dimension at moisture content y. K_{x-y} means the shrinkage from water saturated (x) to a moisture content of y% and Z_{x-y} means the swelling from ovendry (y) to moisture content of x%.

Determination of the durability (SKH Publication 97-04 / CEN/TS 15083-1):
All samples, including virulence samples were conditioned at 20°C, 65% RH to equilibrium. The dry weight of the test samples was determined using the moisture content of 2 samples of each lath. According to the CEN/TS 15083-1 the initial dry weight of the virulence samples was determined using oven drying at 103 °C for 16-24 hours. The conditioned samples were sterilized with ionized radiation.

The samples were placed in culture vessels, which contained sterilised culture medium (agar) which was inoculated with one of the wood destroying Basidiomycetes (Table 2.2). The choice of the test fungi is based on the recommendations from both the SKH Publication 97-04 and CEN/TS 15083-1.

Table 2.2 Fungi used in the test

Fungus	Common name	Type
Coniophora puteana	Cellar (rot) fungus, wet rot fungus	Brown rot
Poria placenta	Pore fungus	Brown rot
Coriolus versicolor	Turkey tail fungus, Shelf fungus, Many zone polypore	White rot
Donkioporia expansa	Oak polypore	White rot

In each culture vessel, two test samples were placed. The culture vessels were then placed in a culture chamber (22°C, 70% RH) for a period of 16 weeks. The virulence control samples were exposed in the same way.
After the exposure period, the samples were taken from the culture vessels and, after removing adhering fungal tissue, they were weighed before and after drying at 103 °C for 16-24 hours.

The mass loss (ML) of each individual sample due to fungal decay was calculated based on the dry weight before and after the test. The moisture content (mc) of the samples was calculated based on the weight before and after drying.

$$ML = \frac{(m_0 - m_t)}{m_0}$$

with:

ML	*mass loss*	*(%)*
m_0	*dry weight of the sample before the test*	*[g]*
m_t	*dry weight of the sample after the test*	*[g]*

$$mc = \frac{(m_{tw} - m_t)}{m_t}$$

with:

mc	*moisture content*	*(%)*
m_{tw}	*wet weight of the sample before oven drying*	*[g]*
m_t	*dry weight of the sample after oven drying*	*[g]*

Following EN 350:2016 the classification into durability classes would be based on the median percentage of mass loss of the test samples. The criteria of the durability classes as defined in the standard are given in Table 2.3. The fungus resulting in the highest mass loss (in %) determines the durability class.

None off the timber species investigated in this study fulfils the demands with regard to the number of samples required in the standard. Table 2.1 gives an overview of the number of samples used per species. Therefore this durability test can only result in an indication of the durability class.

Table 2.3. Durability classification according to EN 350 for Basidiomycete fungal tests

Durability class	Description	Percentage mass loss (ML)				
1	Very durable			ML	≤	5
2	Durable	5	<	ML	≤	10
3	Moderately durable	10	<	ML	≤	15
4	Slightly durable	15	<	ML	≤	30
5	Not durable	30	<	ML		

2.4 Apparatus

- Electric wood moisture meter (SHR/107 and SHR/187)
- Analytic balance (SHR/648 and SHR/008)
- Thickness gauge (SHR/007)
- Electric furnace (SHR/038 and SHR/200)

3 Results

In this chapter the results are given of the lot assessment, swelling and shrinkage and the durability test. The results are grouped by wood species.

In general the wood available was of poor quality: of 4 stems it is suspected that they have been too long in the forest after felling, based on the rot, blue stain and bore holes present in the wood. This makes the available test material partly unusable for further research. As the wood was delivered at SHR undried, two months of drying (at 20°C and 65% RH) with some air movement, was too short to reach moisture contents below 20%. The much smaller samples for shrinkage & swelling and durability tests were therefore dried in a climate chamber at 65%RH and 20°C. After they reached their equilibrium moisture content, further investigation was started. As some of the samples needed more time for climatization, the durability test was executed in two parts.

Regarding the durability test, the CEN/TS 15083-1 fungal test requires the determination of the virulence of the fungi. Sufficient virulence is present when the mass loss of the untreated pine sapwood and / or beech test samples is more than the minimum percentage specified in the CEN/TS 15083-1 (column 'ML required' in Table 3.1).
In this test beech virulence samples were used for all fungi according to the CEN/TS 15083-1.
For some samples it took a long time to reach their equilibrium moisture content. Therefore the test (charge 1) was started without theses samples and the test (charge 2) with these samples was started several weeks later. For charge 1 virulence samples of softwood and hardwood were included for all fungal species. For charge 2 virulence samples were used as required but as *Poria placenta* has a preference for softwood, we used for this species softwood only. Table 3.1 shows the required mass loss and the mass loss (ML) found for all virulence control specimens in this test. Since the test is executed in two parts there are two columns for ML found.

Table 3.1 Required and found mass loss (ML) of virulence samples for the fungi used in the test

Fungus	Type	Wood species	Virulence control samples		
			ML required (%)	ML found (%) charge 1	ML found (%) charge 2
Coniophora puteana	Brown rot	Pine sapwood	> 30	28.0	34.0
		Beech	> 30	38.8	41.6
Poria placenta	Brown rot	Pine sapwood	> 20	16.7	17.5
		Beech	no requirement	14.1	-
Coriolus versicolor	White rot	Pine sapwood	no requirement	18.6	-
		Beech	> 20	36.6	31.0
Donkioporia expansa	White rot	Pine sapwood	no requirement	15.4	-
		Beech	no requirement	19.7	23.5

3.1 Ingipipa

Lot assessment

Below a summary of the lot assessment is given (for further details see appendix 1).

Colour:	light brown with light streaks.
Sapwood:	not clearly demarked: width: 1-10cm
Grain:	straight
Interlocked grain:	not present
Knots:	not present
Checks:	some radial checks, increasing towards the pit. Bark pocket over a length of 30 cm.
Decay:	mainly in the outer side of the sapwood: white rot; numerous boreholes (in the sapwood, as well as in the heartwood).
Remark:	the decay intensity gives the impression that the stem laid in the forest for a long time after felling.

Figure 3.1.1 sawn and planed ingipipa

Anatomical description

Hardwood, diffuse porous, vessel distribution diffuse, vessels solitary and in radial groups of 2 (-5), tangential diameter appr. 150 µm, appr. 5/mm², pits alternate, 6-7 µm in diameter, vessel-ray pits similar but smaller. Fibres average thick walled, non-septate. Parenchyma in apotracheal 1(-2) wide bands, reticulate, 5-8 cells per strand. Rays (1-)2-3-seriate, homogeneous to heterogeneous with one row of marginal cells.

Density, moisture content, shrinkage and swelling

The density at a climatized moisture content (20°C, 65% RH) is given in table 3.1.1. In table 3.1.2 and 3.1.3 the wood moisture contents at respectively descending and ascending relative humidity are given. In table 3.1.4 and 3.1.5 the shrinkage and swelling values are given. Individual data are given in appendix 4.

Table 3.1.1 Density for moisture content as started at 20°C and 65% RH

N=12	Density [kg/m³]	Moisture content (%)
mean (min-max)	744 (723-781)	14.0 (13.5-14.4)
std	20.6	0.3

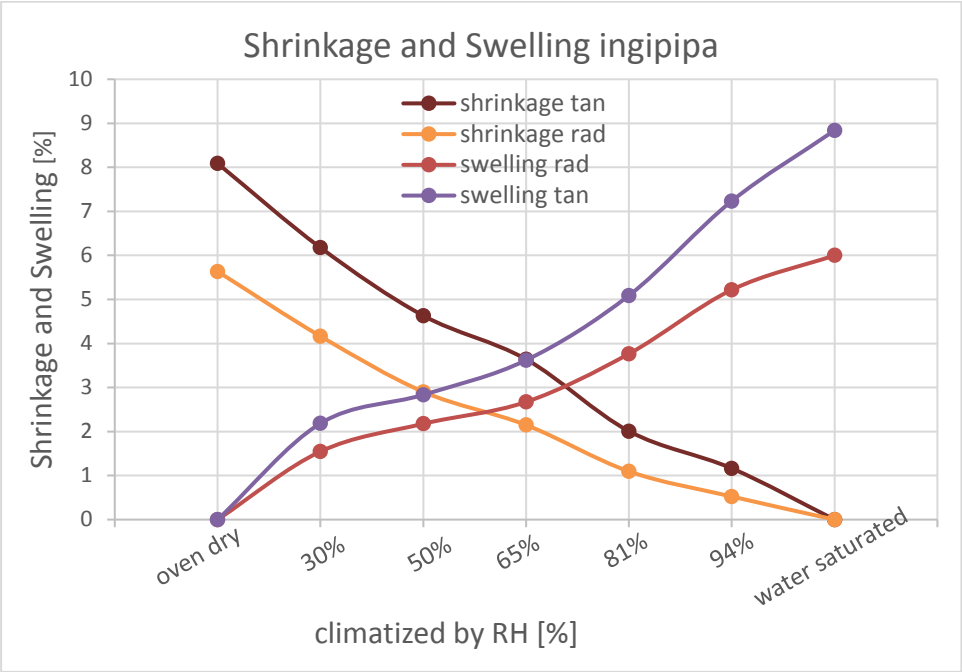

Figure 3.1.2 Shrinkage and swelling of ingipipa climatized at various humidities

The swelling from 50% RH to 95% RH is respectively 3.0% and 4.4% for radial and tangential. The standard deviation is 0.3% and 0.4% respectively.

Durability

The median mass loss of the samples as a result of the exposition to each of the four fungi is given in Table 3.1.6. Also a provisional classification is indicated per fungus based on that single value. All individual sample values are given in Appendix 3.

Table 3.1.6 mass loss and provisional durability class for the different fungi

Fungus	*Coniophora puteana*		*Poria placenta*		*Coriolus versicolor*		*Donkioporia expansa*	
Wood species	**ML (%)**	**DC**	**ML (%)**	**DC**	**ML (%)**	**DC**	**ML (%)**	**DC**
Ingipipa	-0.1	1	-0.1	1	0.7	1	0.2	1

In table 3.1.7 the spread of the individual mass losses are shown, together with the indicative durability class for *Coriolus versicolor*, since *Coriolus versicolor* led to the highest mass loss.

Table 3.1.7 Spread (in %) of individual mass loss values (n = 7) over the durability classes (DC) for *Coriolus versicolor*

1	4	57
2	1	14
3	0	0
4	2	29
5	0	0

3.2 Bostamarinde

Lot assessment

Below a summary of the lot assessment is given (for further details see appendix 1).

Colour:	yellow, in a wengé-like pattern (alternating light and dark zones), little pinkish around the heart.
Sapwood:	not clearly demarked, almost no colour difference: width possibly 3-4.5 cm. locally blue, possibly as reaction to environment
Grain:	straight
Interlocked grain:	distinct and regular
Knots:	in the heart plank two larger knots (Ø 3cm, with bark pocket one knot with some brown rot) also some pin knots
Checks:	Only present in the heart plank
Decay:	white rot in outer side and locally some deep worm holes
Remarks:	some thin canals with extractives present, clear reaction wood; the decay intensity gives the impression that the stem, laid for longer time in the forest after felling

Figure 3.2.1 Bostamarinde heartwood, reaction wood and sapwood

Anatomical description:

Hardwood, diffuse porous, vessel distribution diffuse, solitary and in radial groups of 2-3, tangential diameter 250-350 µm, appr. 10/mm², pits alternate, 4-5 µm in diameter, vessel-rays pits similar but smaller. Fibres average thick walled, non-septate. Parenchyma wavy wide bands (>50% of total structure), 2-4 cells per strand. Rays 2-seriate, homogeneous to heterogeneous with one row of marginal cells.

Density, moisture content, shrinkage and swelling

The density at a moisture content (20°C, 65% RH) is given in table 3.2.1. In table 3.2.2 and 3.2.3 the wood moisture contents at respectively descending and ascending relative humidity are given. In table 3.2.4 and 3.2.5 the shrinkage and swelling values are given. Individual data are given in appendix 4.

Table 3.2.1. Density for moisture content as started at 20°C and 65% RH

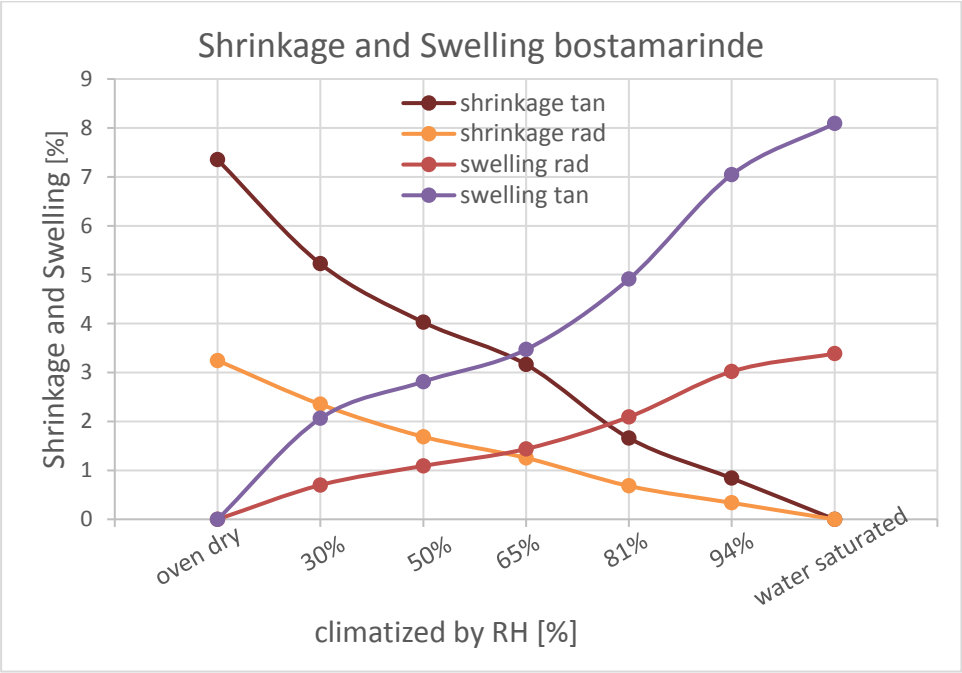

Figure 3.2.2 Shrinkage and swelling of bostamarinde climatized at various humidities

The swelling from 50% RH to 95% RH is respectively 1,9% and 4,4% for radial and tangential. The standard deviation is 0,6% and 1,5% respectively.

Durability

The median mass loss of the samples as a result of the exposition to each of the four fungi is given in Table 3.2.6. Also a provisional classification is indicated per fungus and test group based on that single value. All individual sample values are given in Appendix 3.

Table 3.2.6 mass loss and provisional durability class for the different fungi

Fungus	*Coniophora puteana*		*Poria placenta*		*Coriolus versicolor*		*Donkioporia expansa*

3.3 Gindya-udu

Lot assessment

Below a summary of the lot assessment is given (for further details see appendix 1).

Colour:	red-brown, light striped by lighter streaks, sapwood yellowish, sometimes the outsides of the heartwood lighter (red-yellow streaks) pinkish discolouration around the heart
Sapwood:	3-9cm wide, clearly demarked from heartwood
Grain:	straight
Interlocked grain:	hardly, some reaction wood
Knots:	one knot of 3cm Ø, one knot with Ø 4cm and one heart knot
Checks:	little
Decay:	stem 4: in heartwood places of brown rot and white rot, on one place a bore hole (Ø around 7 mm) in the heartwood with a discolouration reaction around it. Smaller boreholes (Ø around 1mm) in sapwood, as well as blue stain and white rot; stem 6 has some (mainly white) rot in the outside layers
Remarks:	the decay intensity gives the impression that the stems, especially stem 4, laid for longer time in the forest after felling.

Figure 3.3.1 Gindya-udu, sawn and planed

Wood anatomical description

Hardwood, diffuse porous, vessel distribution diffuse, solitary and in radial groups of 2-3, tangential diameter appr. 150 µm, appr. 7/mm², pits alternate, appr. 10 µm in diameter, vestured, vessel-rays pits similar but smaller. Fibres thick walled, non-septate. Parenchyma aliform with long thin to thick wings, 2-4 cells per strand, crystals in chambered cells. Rays uni-seriate, homogeneous.

Density, moisture content, shrinkage and swelling

The density of gindya-udu and moisture content are given in table 3.3.1. In table 3.3.2 and 3.3.3 the wood moisture contents at respectively descending and ascending relative humidity given. In table 3.3.4 and 3.3.5 are the shrinkage and swelling values given. Individual data are given in appendix 4.

Table 3.3.1. Density for moisture content as started at 20°C and 65% RH

N=26	density [kg/m³]	Moisture content (%)
mean (min-max)	1026.6 (959-1081)	14.93 (14.2-15.8)

The swelling from 50% RH to 95% RH is respectively 3.0% and 4.5% for radial and tangential. The standard deviation is 0.2% and 0.4% respectively.

Durability

The median mass loss of the samples as a result of the exposition to each of the four fungi is given in Table 3.3.6. Also a provisional classification is indicated per fungus and test group based on that single value. All individual sample values are given in Appendix 3.

Table 3.3.6 mass loss and provisional durability class for the different fungi

3.4 Pakoeli

Lot assessment

Below a summary of the lot assessment is given (for further details see appendix 1).

Colour:	brown, light striped , yellow sapwood, in 5.2.2.1 transitional wood is visible, dark streaks
Sapwood:	4.5-8 cm wide clearly demarked from heartwood
Grain:	straight
Interlocked grain:	not present
Knots:	little, one heart plank has 7 little knots (Ø 2,5cm)
Checks:	a number of large radial checks, filled with yellow extractives
Decay:	in the sapwood is locally blue stain and white rot present
Remarks:	the decay intensity gives the impression that the stem, laid for longer time in the forest after felling.

Figure 3.4.1 Pakoeli planks, sawn and planed

Wood anatomical description

Hardwood, diffuse porous, vessel distribution diffuse, solitary and in radial groups of 2-10, in long radial groups the middle vessels sometimes smaller, tangential diameter wider vessels 50-200 µm, appr. 10/mm², pits alternate, appr. 10 µm in diameter, vessel-rays pits similar but smaller. Fibres thick walled, non-septate. Parenchyma in 3-5 cells wide bands, 5-8 cells per strand, with yellow extractives in individual cells. Rays 2-3-seriate, homogeneous to heterogeneous with one row of marginal cells.

Density, moisture content, shrinkage and swelling

The density of pakoeli with the moisture content are given in table 3.4.1. In table 3.4.2 and 3.4.3 the wood moisture contents at respectively descending and ascending relative humidity given. In table 3.4.4 and 3.4.5 are the shrinkage and swelling values given. Individual data are given in appendix 4.

3.5 Kimboto

Lot assessment

Below a summary of the lot assessment is given (for further details see appendix 1).

Colour:	homogeneous yellow, brighter areas visible, outside the brighter areas all the wood is more or less blue stained
Sapwood:	indistinct
Grain:	straight
Interlocked grain:	not present
Knots:	not present
Checks:	many, large radial and heart checks
Decay:	stem 7 with boreholes (Ø around 3 mm) surrounded with discoloration / rot; stem 3 with boreholes (Ø around 1 mm, up to 14mm deep in the wood) sometimes with blue stain/ rot surrounding the boreholes. White rot around the heart and diffuse present in the wood
Remarks:	the decay intensity gives the impression that, especially stem 3, laid for longer time in the forest after felling.

Figure 3.5.1 Kimboto planks sawn and planed, blue stain and wane

Wood anatomical description

Hardwood, diffuse porous, vessel distribution diffuse to a radial alignment or dendritic pattern, solitary and in radial groups of 2-10, tangential diameter 50-100 µm, >20/mm², pits alternate, 2-3 µm in diameter, vessel-rays pits simple or similar to intervessel pits but smaller. Fibres thick walled, non-septate. Parenchyma in unregular wavy 1(-2) cells wide bands, 5-9 cells per strand. Rays 2(-3)seriate, appr. 800 µm high, combined rays higher, heterogeneous with one of more rows of marginal cells.

Density, moisture content, shrinkage and swelling

The density of kimboto with the specific moisture content is given in table 3.5.1. In table 3.5.2 and 3.5.3 the wood moisture contents at respectively descending and ascending relative humidity given. In table 3.5.4 and 3.5.5 are the shrinkage and swelling values given. Individual data are given in appendix 4.

4 Discussion

4.1 Ingipipa

Summary of the results originated from 4 plates of one stem:
Wood quality: light brown in colour, light colour variations, sapwood indistinct, almost failure free timber, but decay in outermost layer (stems probably remained long time in forest)
Density at 14% is 744 kg/m³ and variation is low.
Shrinkage radial / tangential is total 5.6% and 8.1%; wet to moisture content of 11.3%, 2.9% and 4.6%.
Durability is variable (57% of samples in class 1, 29% in class 4).

Quarter sawn (scale in cm's)

Flat sawn (scale in cm's)

Cross section, height 5 mm

Compared to the data from literature of tauari (*Couratari spp.)*, our material has the same wood colour and structure and it can be regarded as heavy tauari with similar shrinkage behaviour (literature: total 5.8% and 7.8% and from wet to 12% moisture content of 2.8% and 4.5%). The variability showed by the durability tests is also comparable with the information from the literature. Wood with decay (probably less durable parts of the stem) was excluded from the test and therefore we think that the durability tests show an overestimation over the behaviour of ingipipa against fungal attack.

Additional information from literature: The workability is variable, like the resistance to shipworm since the silica content varies between the different species. The durability varies class 5, and class 4 are reported as well as class 2 for *Tauari branco* with density ≥600 kg/m³ (moisture content 12%); bending related to density (for small clear specimen 50 - 130N/mm^2).

Compared to tauari, our material is homogeneous in density and colour, it also lacks false heart (brown-red in colour) and resin canals filled with black extractives. Tests on additional stems (at least two) provide further support for its homogeneity.
The use of ingipipa is not different from that of tauari but the supposed homogeneity is in favour of ingipipa.

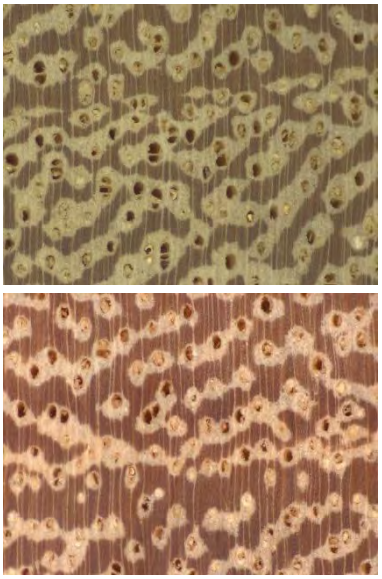
References used: Japing & Japing 1960, Klaassen 2018.

4.2 Bostamarinde

Summary of the results originated from 3 plates of one stem:
Wood quality: yellow in colour, light pinkish around the heart, with darker lines, sapwood indistinct, grain straight, some knots, distinct and regular interlocked grain. Decay in outermost layer and borer holes (stems probably remained long time in forest).
Density at 16% is 573 kg/m³ but variable (450-700 kg/m³).
Shrinkage radial / tangential is total 3.2% and 7.3%; wet to moisture content of 12.6%, 1.7% and 4.0%.
Durability is high with some variation (82% of samples in class 1, 9% in class 2 and 9% in class 4).

Quarter sawn (scale in cm's)

Flat sawn (scale in cm's)



Cross section, height 5 mm

The name bostamarinde is used in Suriname for the genera: *Hydrochorea corymbosa* (synonyms: *Pithecellobium corymbosum, Arthosamanea corymbosa*), *Parkia oppostifolia, Stryphnodendron* and *Martiodendron parviflorum.* The anatomy of first thee species is different from the wood studied. The structure of the last one, also called pintolocus, is similar but it has less clear storied ray arrangement and its heartwood is red-brown in contrast to the pinkish colour we found. In Suriname also the name white pintolocus is used probably referring to whitish heartwood. Additional stems should give more information on the identity of the wood (especially with regard to heartwood formation).

The durability tests show a high resistance against fungi. But we should be careful with conclusions because wood with decay (probably less durable parts of the stem) was excluded from the test and therefore we think that the durability tests show an overestimation over the behaviour of bostamarinde against fungal attack.

If the durability is confirmed with material from additional non-degraded stems, than there are many possibilities for outside use, taking into account the larger difference in radial and tangential shrinkage and the interlocked grain.

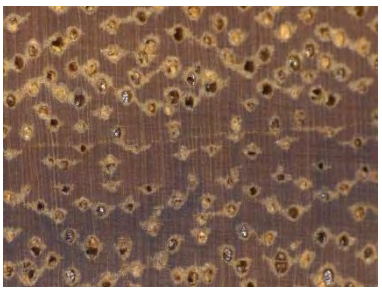
References used: Bhikhi et al 2016, Klaassen 2018.

4.3 Gindya-udu

Summary of the results originated from 2 stem with 3 plates each.
Wood quality: red-brown in colour, colour variations between stems (light and darker), red-yellow streaks and pinkish around the heart, sapwood distinct, some knots, straight grain, some reaction wood, some decay in sapwood and discoloration around bore holes (one stem probably remained long time in the forest).
Density at 15% is 1027 kg/m³ and variation is low.
Shrinkage radial / tangential is total 5.4% and 7.8%; wet to moisture content of 12%, 2.7% and 4.1%.
Durability is high with some variation (83% of samples in class 1, 11% in class 3 and 6% in class 4, lowest values in stem 6).

Quarter sawn (scale in cm's)

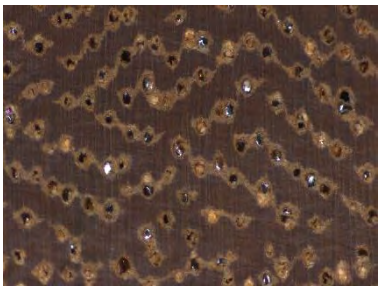
Flat sawn (scale in cm's)



Cross section yellow coloured, height 5 mm

Quarter sawn (scale in cm's)

Flat sawn (scale in cm's)



Cross section brown coloured, height 5 mm

Compared to the data from literature of gindya-udu (*Buchenavia* spp.) our material has the same wood colour and colour variance and structure. The shrinkage behaviour as described in the literature is variable (found values for total radial and tangential of 8% and 12% and for wet to 12% moisture content of 5.5% and 8%, other sources refer to a total shrinkage of 2.8% and 5.6%). Our values are just in between the variation. The durability found in our tests is somewhat higher than found in literature (class 2-3). Wood with decay (probably less durable parts of the stem) was excluded from the test and therefore we think that the durability tests show an overestimation over the resistance of gindya-udu against fungal attack. We suppose also a relationship between durability and colour. Lighter coloured wood seems to be less durable (figure 4.3.1).

References used: Comvalius 2001, Gerard et al. 1996, Klaassen 2018.

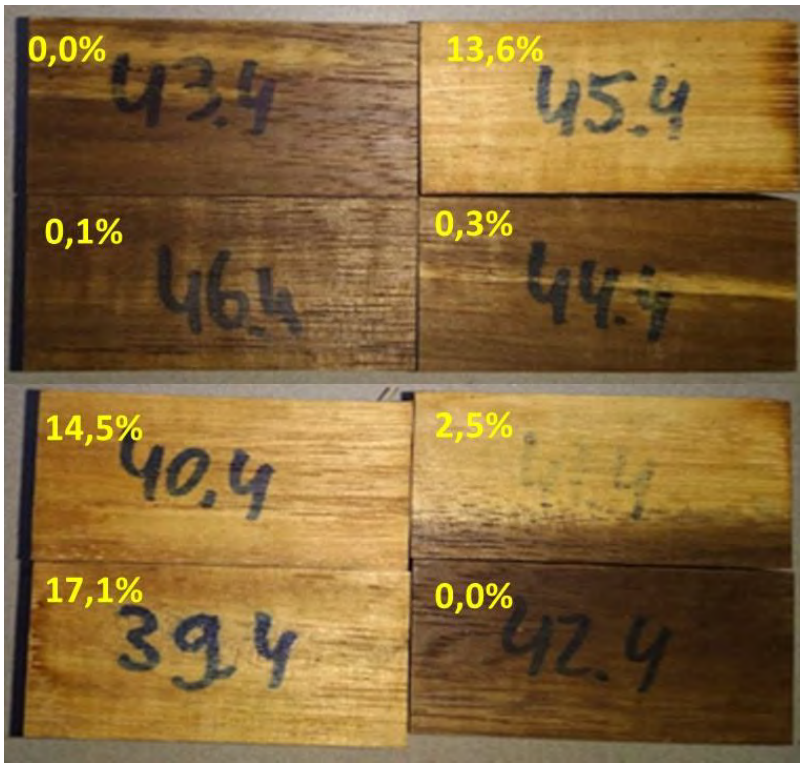


Figure 4.3.1 Mass loss in per percentage because of *Coriolus versicolor* (see Appendix 3 for) and wood colour

4.4 Pakoeli

Summary of the results originated from 2 stems with two plates each.
Wood quality: brown in colour, intermediary wood, sapwood distinct, large cracks (often filled with yellow extractives), small knots, local decay
Density at 14% is 855 kg/m³ and variation is low.
Shrinkage radial / tangential is total 4.5% and 7.9%; wet to moisture content of 11.1%, 2.2% and 4.5%.
Durability is high (100% of samples in class 1).

Quarter sawn (scale in cm's)

Flat sawn (scale in cm's)

Cross section, height 5 mm

Compared to the data from literature of pakoeli (bacuri, *Platonia* spp.*)*, our material has the same wood colour, extractives, structure and shrinkage behaviour (literature: total 4.5% and 9% and from wet to 12% moisture content of 3.0% and 4.5%). The high durability is confirmed by literature.

Additional information from literature: pakoeli has a tendency to distort and check, therefore it should be carefully dried, the workability is good but the variable silica content and hardness has to be taken in consideration.

References used: Comvalius 2001, Gerard et al. 1996, Japing & Japing 1960, Klaassen 2018.

4.5 Kimboto

Summary of the results originated from 4 plates of one stem:
Wood quality: yellow in colour with brighter areas, sapwood indistinct, texture homogeneous, cracks, straight grain, outside the bright area, all the timber is degraded or blue stained. (stems remained long time in forest).
Density at 16% is 872 kg/m³ and some variation.
Shrinkage is large: radial / tangential is total 6.2% and 11.5%; wet to moisture content of 12.7%, 3.3% and 7.5%.
Durability is variable (60% of samples in class 1, 20% in class 3, 20% in class 4).

Quarter sawn (scale in cm's)

Flat sawn (scale in cm's)

Cross section, height 5 mm

Compared to the data from literature of kimboto (casca, *Pradosia* spp.*)*, our material has the same wood colour, structure, shrinkage behaviour (literature: total 6.9% and 11.3% and from wet to 12% moisture content of 3.5% and 6.5%) and sensitivity to blue stain The high or moderate durability is not confirmed by literature (probably due to forest exposition of our material).

Additional information from literature: workability is not easy due to the silica content and hardness. It is recorded that the timber is suitable for inside heavy constructions, house framing, floors and furniture.

5 Conclusion

The five timber species from Suriname were investigated according to Dutch standard (SKH Publication 97-04) in order to get an idea of their properties and use potential. This standard is developed to get a first impression of the use potential of lesser and unknown timber species specific for joinery but also for timber use in general.

For all applications it is important to know the botanical identity of the timbers as properties are species related. Therefore descriptions of the structure and pictures of the three main wood surfaces have to be available in order to make sure that clear recognition is possible. For all five species these descriptions and pictures were made and compared with literature. The identity of four species was confirmed and the data on their properties were collected. Descriptions of bostamarinde in literature are contradicting and limited and therefore it was impossible to make a clear identification of this species .

The available wood quality of each species is an important item to determine its use potential. Failure free large and thick boards have a large potential whereas the potential is very limited for small boards with many failures (e.g. knots, sapwood, deviant grain, cracks) although its properties could be excellent. In order to get a good idea of the wood quality at least 27 boards originating from at least 3 different trees are required. In this study one stem only was available for pakoeli, bostamarinde, and ingipipa. Two stems only were available for gindya-udu and kimboto. Therefore the wood quality determined of each of the species should be regarded as a first impression of the potential quality to be expected on the Dutch and other foreign markets. The wood quality of all five investigated species is promising but large checks appeared in ingipipa, kimboto, and pakoeli and these should be avoided by a more careful handling avoiding too fast drying.

The first impression of the wood quality, density and dimension stability shows that the Surinam ingipipa compared to its South American relatives is more homogeneous, the Surinam gindya-udu is more variable, and the Surinam kimboto and pakoeli are similar to the information found in the literature. For gindya-udu selection on quality could improve the homogeneity.
Although bostamarinde could not be identified as such, the material investigated shows reaction wood, interlocked grain, and decay, suggesting specific use with requirement of careful handling and selection on quality.

The resistance against fungal decay of a wood species is difficult to describe because it varies with how the timber is used and with different locations of the wood in the tree. In soil contact other wood degrading fungi are active than in timber use above the ground. Therefore there are different standards to test the resistance against fungal decay, accelerated tests with and without soil contact and field tests. The Dutch standard used here, (focussing on joinery), demands an accelerated test without soil contact. All stems in at least some parts, of the species tested here, show some decay. Presence of decay in wood samples for the durability test is not allowed in these tests and therefore only sound timber was selected. The samples used in the durability test therefore give an overestimation of the resistance against fungal decay and do not represent the full variation of the species. The results of the test therefore only give an idea of the durability of the species. In this conclusion no classification can be mentioned because the number of samples did not fulfil the requirements of the standard.

The information of the wood quality and durability is too limited for a clear statement of use potential.

Summary per species

The summary below gives a preliminary estimation of the use potential per species, based on the available data (this project and literature) and the expectation based on the quality of more and representative sample material:

- Surinam ingipipa: if a lower tangential shrinkage and a higher durability can be proven, then the species could be suitable for outside joinery, if a higher durability cannot be proven then only inside use is possible.
- Surinam bostamarinde: if the identity of the species is known and a quality selection can provide timber without reaction wood, it has potential for inside use.
- Surinam gindya-udu: the species could have potential for ground and water constructions.
- Surinam pakoeli: the species could have potential for ground and water constructions.
- Surinam kimboto: the species has potential for inside use but only in decay/blue stain free qualities.
-

Recommendations

Research on eight additional stems (so for every species in total 3 stems are tested) should be done and the results should be included in the data already available. With this extension clear scientifically sound statements on durability and use potential of each of the Surinam timber species can be made and the identity of bostamarinde can be confirmed.

Appendix 1 Lot assessment

Ingipipa (stem 1)
Below the available ingipipa is described based on the lot assessment.

Stem 1	plate 1: 3 beams 13x7cm, 16,5x7cm and 17x7.5cm (1 with wane)	
	plate 2: 3 beams 18x7cm, 17x7cm and 17x7cm	
	plate 3: 2 beams 17.5x8cm and 17.5x8cm (1 with wane)	
	plate 4: 3 beams 16x8cm, 17.5x8cm and 18.5x8cm	
Colour:		light brown with light streaks
Sapwood:		not clearly demarked: width: 1.1.1.1 (8cm); 1.1.1.2 (10cm); 1.1.2.1 (1,5 cm); 1.1.3.1 (4 cm to wane); 1.1.4.2 (1 cm)
Grain:		straight
Interlocked grain:		not present
texture:		light striped
Knots:		not present
Checks:		Some radial checks, increasing towards the pit. Bark pocket over a length of 30cm
Decay:		Mainly in the outer side of the sapwood, a lot of white rot in the sapwood, numerous boreholes in the sapwood, but as well in the heartwood 1.1.1 and 1.1.3 are not suitable for further research (white rot and bore holes) partially useable is 1.1.4 (parts decayed by white rot)
Remarks:		Possible stem 1 has been too long in the forest after felling.

Plate 3

Plate 1 side

Plate 3

Plate 4

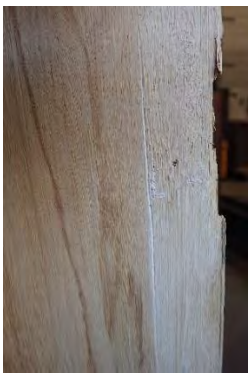
Plate 4

Bostamarinde (stem 2)

Below the available bostamarinde is described based on the lot assessment.

Stem 2.1	plate 1: 2 beams 23x7.7cm and 21x7.5cm (1 with wane, 1 with boxed heart) plate 2: 3 beams 24x7cm, 18x7cm and 24x7 cm plate 3: 3 beams 22x7.5cm, 23x7.5cm and 24x7.5 cm (2 with wane)
Colour:	yellow, little pinkish around the heart
Sapwood:	not clearly demarked no colour difference: width possible 3-4.5cm. locally blue, possibly as reaction to environment (present in 2.1.3.2, 2.1.3.1 and 2.1.1.1)
Grain:	straight
Interlocked grain:	distinct and regular
Texture:	besides interlocked grain also a wengé-like pattern (alternating light and dark zones)
Knots:	in the heart plank two larger knots (Ø 3cm, with bark pocket one knot with some brown rot) also some pin knots
Checks:	Only present in the heart plank
Decay:	white rot in outer side (sapwood) and locally deeper (2.1.3.2, 2.1.3.1 and 2.1.1.1). only deeper in 2.1.2.1 and 2.1.2.2. worm only (little) present in sapwood
Remarks:	At the transition from sapwood to heartwood is a thin canal with extractives present. Possibly a lot of reaction wood.

Sapwood with worm

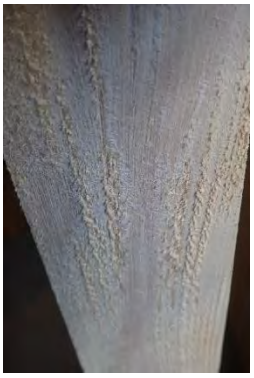


Narrow line with extractives between heart- and sapwood

Striped texture

Heart plank with check

Reaction wood



Reaction wood detail

Gindya-udu (stem 4 and 6)

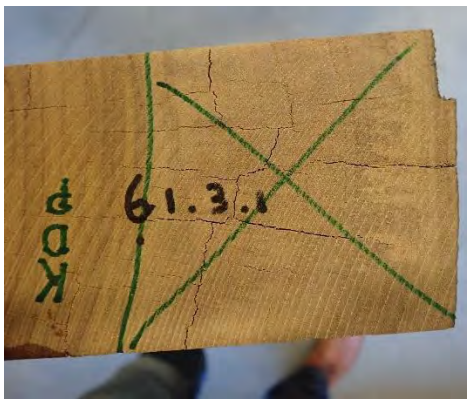
Stem 4.1	plate 1: 4 beams 11x4cm, 7.5x4cm, 12.5x4cm and 7x4cm (2 with wane, 2 with sapwood) plate 2: 3 beams 12x7cm, 14.5x7cm and 15x7cm (1 with wane, 2 with sapwood) plate 3: 3 beams 14.5x5cm, 15.5x5.5cm and 11.5x5.5cm (1 with wane, 2 with sapwood)
Stem 6.1	plate 1: 3 beams 10x4.57cm and 12x9.5cm (2 met wane and sapwood) plate 2: 2 beams 14.5x3.5cm and 15.5x3.5cm (1 with sapwood) plate 3: 3 beams 17.5x7.5cm, 17.5x7.5cm and 17.5x7.5 cm (1 met wane, 1 with heart, 2 with sapwood)
Colour:	red-brown, sapwood yellowish, sometimes the outsides of the heartwood lighter (red-yellow streaks) pinkish discolouration around the heart
Sapwood:	3-9cm wide, clearly demarked from heartwood
Grain:	straight
Interlocked grain:	hardly, some reaction wood
Texture:	light striped by lighter streaks
Knots:	one knot of 3cm Ø, one knot with Ø 4cm and one heart knot
Checks:	little
Decay:	stem 4: in heartwood places of brown rot and white rot, on one place a bore hole (Ø around 7 mm) in the heartwood with a colouration reaction around it. Smaller boreholes (Ø around 1mm) in sapwood, as well as blue stain and white rot. For stem 6 it is mainly (white)rot in the outside
Remarks:	possible stem 4 has been too long in the forest after felling.

Stem 4

Borehole

White rot in heartwood

Stem 6



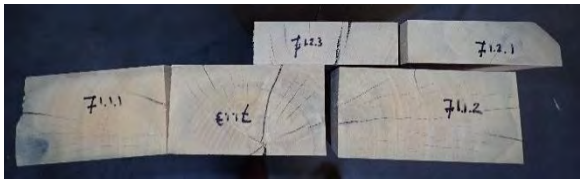
Cross section, wane, sapwood, drying checks, decay

Overgrown injury

Overgrown injury detail

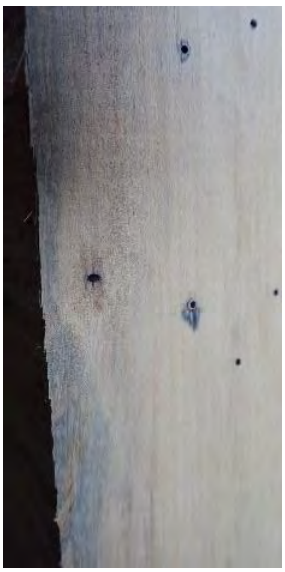
Kimboto (stem 3 and 7)

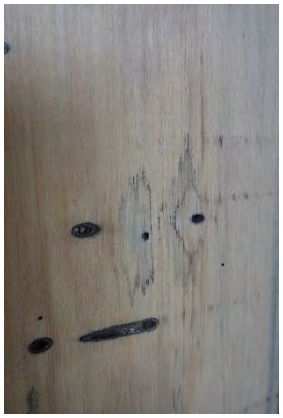
Stem 3.1	plate 1: 3 beams 14x4cm, 14x4cm and 14x4cm (2 with wane)
Stem 3.2	plate 2: 2 beams 17.5x7,5cm and 17.5x7.5cm (1 with boxed heart)
Stem 7.1	plate 1: 2 beams 15x4.5cm and 14.5x4.5cm (1 with wane) plate 2: 3 beams 17.5x8.5cm, 15x8.5cm, 15x8.5cm (1 with boxed heart, 1 with wane)
Colour:	yellow, brighter areas visible, sapwood invisible, outside the brighter areas al the wood is more or less blue stained.
Sapwood:	invisible
Grain:	straight
Interlocked grain:	not present
Texture:	homogeneous
Knots:	not present
Checks:	many, large radial and heart checks
Decay:	stem 7 with boreholes (Ø around 3 mm) surrounded with colouration / rot; stem 3 with boreholes (Ø around 1 mm, up to 14mm deep in the wood) sometimes with bleu stain/ rot surrounding the boreholes. White rot around the heart and diffuse present in the wood
Remarks:	possible stem 3 has been too long in the forest after felling.



Checks and blue stain

Boreholes with blue stain (rot)





Boreholes

Pakoeli (stem 5)

Stem 5.1	plate 1: 3 beams 14x4.5cm, 12.5x4.5cm and 11x4.5cm (1 with wane, 2 with sapwood) plate 2: 3 beams 19x8.5cm, 15x8.5cm and 13x8.5cm (1 with wane, 2 with sapwood, 1 with boxed heart)
Stem 5.2	plate 1: 3 beams 15.5x7.5cm, 15.5x7.5cm and 16x7.5cm (1 with wane, 2 with sapwood, 1 with boxed heart) plate 2: 3 beams 12x4.5cm, 13x4.5cm and 14x7.5cm (2 with wane, 2 with sapwood)

Colour:	brown, yellow sapwood, in 5.2.2.1 transitional wood is visible, dark streaks
Sapwood:	4.5-8cm wide clearly demarked from heartwood
Grain:	straight
Interlocked grain:	not present
Texture:	light striped
Knots:	little, one heart plank 7 little knots (Ø 2.5cm)
Checks:	a number of large radial checks, filled with yellow extractives
Decay:	the sapwood is locally bleu stained and/or rot
Remarks:	possible the stem has been too long in the forest after felling.
